## New York City

 Population Projections by Age/Sex \& Borough, 2010-2040

# New York City Population Projections by Age/Sex \& Borough, 2010-2040 

THE CITY OF NEW YORK Michael R. Bloomberg, Mayor

DEPARTMENT OF CITY PLANNING
Amanda M. Burden, faice, Director

22 Reade Street
New York, NY 10007-1216 nyc.gov/population

## ACKNOWLEDGMENTS

Joseph J. Salvo, Arun Peter Lobo, and Erica Maurer of the Population Division executed these population projections and demographic analyses, and wrote the accompanying report.

Adam Attar, Joel Alvarez, Donnise Hurley, Will Levin, Anna Triebwasser, Johanna Lovecchio, and Tamara Agins helped review the document. The report was prepared under the general direction of Eric Kober, Director of the Housing, Economic and Infrastructure Planning Division of the New York City Department of City Planning.

The borough offices of the Department provided detailed feedback on issues related to land use and zoning. We thank the Directors and Deputy Directors of each of the borough offices (as well as their staff): Carol Samol and Ryan Singer of the Bronx office, Purnima Kapur and Winston Von Engel of the Brooklyn office, Edith Hsu-Chen and Adam Wolff of the Manhattan office, John Young and Deborah Carney of the Queens office, and Len Garcia-Duran and Nicole Campo of the Staten Island office.

We are grateful for the technical assistance provided by Robert Scardamalia, the former Chief Demographer for the New York State Department of Economic Development.

# New York City Population Projections by Age/Sex \& Borough, 2010-2040 

## Introduction

This report presents an analysis of New York City's population projected from 2010 through 2040. These projections were done for each of the city's five boroughs by age and sex, at five year intervals for this 30 year period.

These 2013 projections update the Department of City Planning's earlier population projections published in 2006, ${ }^{1}$ which projected New York City's population at 9.1 million in 2030. The 2006 projections were an important input to PlaNYC 2030. ${ }^{2}$

Both the 2006 and the current (2013) projections were created using a cohort component model, which breaks down population growth into three main components: births, deaths, and migration. The cohort component model uses these three components to move age/sex cohorts forward through time, creating a new age/sex distribution at each five year time point (Figure 1). A particular cohort's ability to grow or decline is tied to how the three components affect each age/sex group. The success of the model depends on identifying appropriate fertility, mortality, and migration rates to apply to different age groups. The experience of age cohorts (persons born over a specified period) can be followed on each diagonal in the model. This means that any changes in the number of persons along each diagonal are not due to changes in the size of the birth cohorts, but to the effects of aging and/or migration.

Figure 1: The Cohort Component Model

| 2010 | 2015 | 2020 | 2025 | 2030 | 2035 | 2040 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| $55-59$ |  |  |  |  |  | $55-59$ |

Arrow shows 25-29 year old female cohort aging through time

The cohort component model is the most widely used projection method because the demographic components that are applied to each cohort interact with each other, resulting in a more realistic outcome. For example, if there were large numbers of 25-29 year old female in-migrants, the $25-$ 29 year old female cohort would grow from the net positive migration. There would also be increased growth in the $0-4$ cohort since these women are in their prime child-bearing ages. These types of relationships within the model make it both realistic and complex because each of the components interacts with the others to affect the age structure of the population.

While the projections were developed using demographic methods, by themselves such methods are not sufficient for the creation of useful projections, as they need to be examined in the context of the city's planning environment. Of the three demographic components used in the cohort component model, births and deaths can be modeled by demographers with a relatively high degree of confidence, based on the age structure of the population, but migration is far more variable and unpredictable. When projecting population increase over several decades, demographers need in effect to select a rate of net migration, from a wide range of possibilities. For these projections, migration rates were closely analyzed to ensure that the resulting projection of population and housing could be reasonably accommodated, given the city's current land use and zoning. In addition to land use and zoning constraints, high population densities,
fixed political boundaries, and the high cost of residential construction also act to limit population growth. Thus, migration rates in the demographic model are adjusted based on this planning component, which ensures that the city's land use and zoning can accommodate projected population growth (see Appendix I).

When the PlaNYC projections were created, they were first benchmarked on the Census Bureau's 2005 estimate of the city's population, which was over 8.2 million. The city was in the midst of a building boom during this period, with new housing permits exceeding 30,000 housing units in 2005, compared with just 5,100 units 10 years earlier. As a result, a series of ambitious assumptions were adopted, sending the population projection to 8.4 million in 2010. However, with the national economic recession beginning in late 2007, many of these permits became completed housing units much later than expected, or were never completed at all. By 2010, the decennial census enumerated the city's population at less than 8.2 million, or at 8.24 million when adjusting for the undercount (see Appendix I).

The projections developed for PlaNYC had the city's population at 8.4 million in 2010, 8.7 million in 2020, and 9.1 million in 2030. The 2010 "base" ${ }^{3}$ population in the current projections is just 8.24 million, making it impossible to reach the earlier 2020 projection of 8.7 million. The city's population is now projected to reach 8.55 million in 2020. With a lower population projected for 2020, it is apparent that the initial PlaNYC projection for 2030 is no longer realistic. Thus, reaching a population of 9 million, originally projected for 2030, is now projected to occur by 2040. The new population projection for 2030 is 8.8 million, with a rise to 9.03 million in 2040.

This report has three sections. The first section presents population projections for 2010-2040 for the total population of the city and the five boroughs. The section focuses on projections for persons of school-age ( 5 to 17 years) and those 65 years and over. It also includes a discussion of the planning/housing component that was used to corroborate the cohort-component projections. The second section discusses these projections in the context of New York City's recent demographic past (1950-2010). The third section consists of two detailed appendices. Appendix I presents the underlying demographic assumptions made in these projections along with a detailed description of the data and methodology employed. While the projections in this report focus primarily on the total population, those of school-age, and the population 65 and over, Appendix II of this report provides detailed tables with projected populations for all age groups by sex and by borough.

## Population Projections: 2010-2040

## Total Population

New York City is projected to grow from 8.2 million persons in 2010 to 9 million in 2040, an increase of 783,000 or 9.5 percent. ${ }^{4}$ In 2010-2020, the first decade of the projection, New York City's population is projected to increase by 3.7 percent, but growth is expected to slow to 3.2 percent in the following decade, with the population reaching $8,821,000$ in 2030. Between 2030 and 2040, the growth rate in New York City is projected to decrease once again to 2.3 percent (Table 1).

In Manhattan, Queens, and Staten Island, the highest level of growth is projected to be in the 2010-2020 period, with growth slowing thereafter. In the Bronx and Brooklyn, however, the highest growth rates are projected to occur one decade later, between 2020 and 2030. In the final decade, 2030-2040, growth is projected to slow in all five boroughs, with growth rates at their lowest levels for the entire projection period.

Table 1: Projected Total New York City Population by Borough, 2010-2040

|  | $\underline{2010}$ | $\underline{2020}$ | $\underline{2030}$ | $\underline{2040}$ | CHANGE |  |  |  |  |  |  |  |

| NYC | 8,242,624 | 8,550,971 | 8,821,027 | 9,025,145 | 308,347 | 3.7 | 270,056 | 3.2 | 204,118 | 2.3 | 782,521 | 9.5 |
| Bronx | 1,385,108 | 1,446,788 | 1,518,998 | 1,579,245 | 61,680 | 4.5 | 72,210 | 5.0 | 60,247 | 4.0 | 194,137 | 14.0 |
| Brooklyn | 2,552,911 | 2,648,452 | 2,754,009 | 2,840,525 | 95,541 | 3.7 | 105,557 | 4.0 | 86,516 | 3.1 | 287,614 | 11.3 |
| Manhattan | 1,585,873 | 1,638,281 | 1,676,720 | 1,691,617 | 52,408 | 3.3 | 38,439 | 2.3 | 14,897 | 0.9 | 105,744 | 6.7 |
| Queens | 2,250,002 | 2,330,295 | 2,373,551 | 2,412,649 | 80,293 | 3.6 | 43,256 | 1.9 | 39,098 | 1.6 | 162,647 | 7.2 |
| Staten Island | 468,730 | 487,155 | 497,749 | 501,109 | 18,425 | 3.9 | 10,594 | 2.2 | 3,360 | 0.7 | 32,379 | 6.9 |

The Bronx is projected to grow from $1,385,000$ in 2010 to $1,579,000$ in 2040, an increase of 14 percent-the highest level of growth among the city's boroughs. After experiencing growth of 4.5 percent in the 2010-2020 period, growth in the borough is projected to increase to 5 percent in the subsequent decade and then decline to 4 percent between 2030 and 2040.

Brooklyn's population, which stood at 2,553,000 in 2010, is projected to grow to $2,841,000$ in 2040, an increase of 288,000 or 11.3 percent. With respect to growth by decade, Brooklyn's population is projected to increase by 3.7 percent between 2010 and 2020, followed by a 4 percent increase in the subsequent decade. Growth is expected to decrease to 3.1 percent between 2030 and 2040. Compared with other boroughs, Brooklyn will have the second highest level of growth and will continue to have the largest population through 2040.

The population in Queens is projected to grow by 7.2 percent, from 2,250,000 in 2010 to 2,413,000 in 2040. The growth between 2010 and 2020 is projected to be 3.6 percent, bringing the population to $2,330,000$ in 2020 . The growth rate is projected to fall to 1.9 percent between 2020 and 2030, and to further decline to 1.6 percent in the following decade.

Between 2010 and 2040, Staten Island is expected to increase from 469,000 to 501,000 , or by 6.9 percent. In the first decade, the borough is projected to grow 3.9 percent, to 487,000 in 2020 . Growth is then projected to fall to 2.2 percent in the following decade, and further decline to 0.7 percent between 2030 and 2040.

Manhattan is projected to grow from 1,586,000 in 2010 to $1,691,600$ in 2040, an increase of 6.7 percent or 106,000 people. Manhattan's population is projected to grow by 3.3 percent between 2010 and 2020, and growth is expected to taper off to 2.3 percent between 2020 and 2030, and to 0.9 percent in the following decade.

## School-Age Population

Table 2 displays the overall number of school-age children (ages 5 to 17) by borough in 2010, as well as the projected school-age population for each decade through 2040. The school-age population, which stood at 1,260,000 in 2010, is projected to increase modestly ( 1.8 percent) over the current decade, reaching $1,283,000$ in 2020; it is projected to grow 5 percent to $1,347,000$ by 2030. Larger cohorts of women born in the late 1980s and early 1990s, along with modest positive net migration in the older school-age population are driving these changes. By 2040, however, the school-age population is projected to dip slightly to $1,342,000$ (a 0.4 percent decline). Given the higher growth of the overall population, the share of school-age children is projected to decline from 15.3 percent in 2010 to 14.9 percent in 2040 (Table 3).

Table 2: Projected New York City School-Age Population by Borough, 2010-2040

|  | $\underline{2010}$ | $\underline{2020}$ | $\underline{2030}$ | $\underline{2040}$ | CHANGE |  |  |  |  |  |  |  |

| Brooklyn | 424,704 | 441,049 | 461,688 | 454,949 | 16,345 | 3.8 | 20,639 | 4.7 | -6,739 | -1.5 | 30,245 | 7.1 |
| Manhattan | 157,856 | 162,931 | 177,440 | 170,114 | 5,075 | 3.2 | 14,509 | 8.9 | -7,326 | -4.1 | 12,258 | 7.8 |
| Queens | 331,926 | 341,062 | 350,544 | 355,340 | 9,137 | 2.8 | 9,482 | 2.8 | 4,796 | 1.4 | 23,414 | 7.1 |
| Staten Island | 80,862 | 78,759 | 79,535 | 80,005 | -2,103 | -2.6 | 776 | 1.0 | 471 | 0.6 | -857 | -1.1 |

Table 3: Projected School-Age Population as a Percent of Total Population by Borough, 2010-2040

|  | $\underline{2010}$ | $\underline{2020}$ | $\underline{2030}$ | $\underline{2040}$ |
| :--- | ---: | ---: | ---: | ---: |
| NYC | 15.3 | 15.0 | 15.3 | 14.9 |
| Bronx | 19.1 | 17.9 | 18.3 | 17.8 |
| Brooklyn | 16.6 | 16.7 | 16.8 | 16.0 |
| Manhattan | 10.0 | 9.9 | 10.6 | 10.1 |
| Queens | 14.8 | 14.6 | 14.8 | 14.7 |
| Staten Island | 17.3 | 16.2 | 16.0 | 16.0 |

Manhattan is projected to see the largest overall percentage increase in school-age children between 2010 and 2040 ( 7.8 percent), followed closely by Brooklyn and Queens (7.1 percent each). Manhattan's school-age population is projected to grow from 158,000 in 2010 to 170,000 in 2040 . Brooklyn is projected to grow from 425,000 in 2010 to 455,000 in 2040. Queens, which in 2010 had the second largest school-age population after Brooklyn, will see its school-age population grow from 332,000 in 2010 to 355,000 in 2040. The Bronx is projected to have a 6.3 percent increase, from 265,000 in 2010 to 282,000 in 2040. Staten Island is the only borough that is not expected to change much over the projection period. The projections show a slight decline in school-age population, from 81,000 in 2010 to about 80,000 ( -1.1 percent) in 2040. Though the school-age population in most boroughs will be growing over time, other age groups are expected to increase even faster. As a result, the share of the school-age population in the Bronx, Brooklyn, and Staten Island is expected to decline between 2010 and 2040, with the share remaining largely unchanged in Manhattan and Queens.

The five boroughs display important differences in each decade of the projection period. The school-age populations in the Bronx and Staten Island are expected to decline in the current decade, by 2.3 percent and 2.6 percent, respectively. In contrast, Brooklyn is expected to see a 3.8 percent increase this decade, followed by Manhattan ( 3.2 percent), and Queens ( 2.8 percent). The highest growth, however, is projected to occur in 2020-2030 when each borough will gain a sizable number of school-age children. Manhattan is projected to grow the most between 2020 and 2030, with an increase of 8.9 percent, or 15,000 school-age children. The Bronx is projected to grow by 7.3 percent, an increase of 19,000 school-age children, offsetting losses in the previous decade. The school-age population in Brooklyn is projected to increase by 21,000 , or 4.7 percent, while that of Queens is projected to grow by 2.8 percent, an increase of 9,000 school-age children. Staten Island will see only a modest change in its school-age population, increasing from 79,000 to 80,000 .

In the final decade of the projection period (2030 to 2040), the overall school-age population is projected to decline in Manhattan and Brooklyn by 4.1 and 1.5 percent, respectively. These losses, however, are expected to be partially offset by increases in the Bronx and Queens (1.4 percent each), and a modest increase in Staten Island ( 0.6 percent).

## Population 65 Years and Over

The population 65 years and over (also referred to as the population $65+$ ) stood at $1,002,000$ in 2010 and is projected to increase to $1,410,000$ in 2040-a jump of 408,000 persons or 40.7 percent. The bulk of the increase is expected to occur in the first two decades of the projection period (Table 4). In the first decade, the population $65+$ is expected to increase by 175,000 or 17.5 percent, and by a still robust 15.9 percent ( 187,000 persons) between 2020 and 2030. In the final decade of the projection period (2030 to 2040), continued, but far slower growth of the population $65+$ is projected-46,000 persons or 3.3 percent. In that decade, the youngest post-World War II "baby boomers" (those born between 1946 and 1964) will be at least 65 years old. In addition, increasing longevity in the projection period allows more people to survive into the older age intervals, thereby boosting their numbers. ${ }^{5}$ All told, the share of the population $65+$ is projected to increase from 12.2 percent in 2010 to 15.6 percent in 2040 (Table 5).

Staten Island is expected to have by far the largest relative increase of any borough in the present decade, with the population $65+$ increasing 30.8 percent between 2010 and 2020. Brooklyn's population $65+$ is expected to increase by 19.3 percent, while that of the Bronx and Manhattan will each increase by about 17 percent. Queens is expected to see the lowest increase, 12.9 percent.

Table 4: Projected New York City 65 and Over Population by Borough, 2010-2040

|  | $\underline{2010}$ | $\underline{2020}$ | $\underline{2030}$ | $\underline{2040}$ | CHANGE |  |  |  |  |  |  |  |

|  |  |  |  |  | 2010-2020 |  | 2020-2030 |  | 2030-2040 |  | 2010-2040 |  |
|  |  |  |  |  | Number | Percent | Number | Percent | Number | Percent | Number | Percent |
| NYC | 1,002,208 | 1,177,215 | 1,364,178 | 1,409,708 | 175,007 | 17.5 | 186,963 | 15.9 | 45,530 | 3.3 | 407,500 | 40.7 |
| Bronx | 145,882 | 171,856 | 212,334 | 228,476 | 25,974 | 17.8 | 40,478 | 23.6 | 16,142 | 7.6 | 82,594 | 56.6 |
| Brooklyn | 294,610 | 351,609 | 408,424 | 428,845 | 56,999 | 19.3 | 56,815 | 16.2 | 20,421 | 5.0 | 134,235 | 45.6 |
| Manhattan | 214,153 | 250,806 | 278,043 | 277,444 | 36,653 | 17.1 | 27,237 | 10.9 | -599 | -0.2 | 63,291 | 29.6 |
| Queens | 288,219 | 325,300 | 370,214 | 377,060 | 37,081 | 12.9 | 44,914 | 13.8 | 6,846 | 1.8 | 88,841 | 30.8 |
| Staten Island | 59,344 | 77,644 | 95,163 | 97,883 | 18,300 | 30.8 | 17,519 | 22.6 | 2,720 | 2.9 | 38,539 | 64.9 |

After 2020, all boroughs will continue to see substantial increases in the size of the population $65+$. The Bronx and Staten Island will each see this population increase by about 23 percent, bringing the $65+$ population in the Bronx to 172,000 and Staten Island's to 78,000 . The next largest increase is projected to occur in Brooklyn, at 16.2 percent, or an increase of 57,000 to 408,000 in 2030. The $65+$ population in Queens is projected to grow by 45,000 between 2020 and 2030, increasing by 13.8 percent to 370,000 in 2030. Manhattan will grow at the slowest rate this decade, but still by a sizable 10.9 percent, bringing its $65+$ population up to 278,000 in 2030.

As mentioned above, the rate of increase in the population $65+$ is projected to slow dramatically in the last decade of the projection period (2030 to 2040), except in Manhattan where this population will remain unchanged. Relative growth is expected to be the highest in the Bronx at 7.6 percent (up from 212,000 to 228,000), followed by Brooklyn at 5 percent (from 408,000 to 429,000 ), Staten Island at 2.9 percent $(95,000$ to 98,000$)$, and Queens at 1.8 percent ( 370,000 to 377,000 ).

Table 5: Projected 65 and Over Population as a Percent of Total Population by Borough, 2010-2040

|  | $\underline{2010}$ | $\underline{2020}$ | $\underline{2030}$ | $\underline{2040}$ |
| :--- | ---: | ---: | ---: | ---: |
| NYC | 12.2 | 13.8 | 15.5 | 15.6 |
| Bronx | 10.5 | 11.9 | 14.0 | 14.5 |
| Brooklyn | 11.5 | 13.3 | 14.8 | 15.1 |
| Manhattan | 13.5 | 15.3 | 16.6 | 16.4 |
| Queens | 12.8 | 14.0 | 15.6 | 15.6 |
| Staten Island | 12.7 | 15.9 | 19.1 | 19.5 |

The increasing importance of persons $65+$ can be seen in their share of each borough's population (Table 5). In 2040, the share of the population 65+ is projected to be highest in Staten Island-almost one-fifth of its population, with each of the other boroughs in the 15 to 16 percent range.

## Housing Units

The results from the cohort-component projection, while very useful, do not project conditions "on the ground," such as the housing needed to accommodate projected population increases. The estimates of housing required to accommodate the demographic projections were developed using a model that includes average household size, assumptions about vacancy rates, and group quarters population, the details of which are provided in Appendix I.

New York City's total housing unit count, which stood at $3,375,000$ in 2010 , is projected to increase by 9.5 percent, bringing the housing unit count to $3,696,000$ by 2040 (Table 6). The Bronx is projected to have the largest percent increase between 2010 and 2040, 14.5 percent, with the total housing unit count in the Bronx increasing from 512,000 in 2010 to 586,000 in 2040. Brooklyn, which had just over 1 million housing units in 2010 - the most of any borough - is projected to grow by 11.4 percent to $1,115,000$ units in 2040. Manhattan, Queens, and Staten Island, with more limited growth potential, are each projected to increase by 7 percent between 2010 and 2040.

Table 6: Projected Total New York City Housing Units by Borough, 2010-2040

## New York City: Past, Present, and Future

In order to provide a better understanding of the city's future demographic landscape, it is useful to examine projected population changes in the context of the city's recent demographic past.

## New York City Population, 1950-2040

New York City's official population as of April 1, 2010 was $8,175,000$, which represented an increase of just 2.1 percent over the figure of $8,008,000$ for 2000. This was well below estimates prepared by New York City in cooperation with the Census Bureau. Part of the reason for this shortfall was the erroneous classification of housing units as vacant in southern Brooklyn and northwest Queens. ${ }^{6}$ As a result, an adjustment to the population was implemented to compensate for this shortfall, which raised the 2010 population to 8.2 million. ${ }^{7}$

While New York City's population grew each decade in the first half of the 20th century, the population declined from nearly 7.9 million in 1950 to under 7.8 million in 1960 (Figure 2 and Table 7). High baby boom fertility and domestic inflows in the 1950s did not fully counter the large out-migration to the suburbs, and growth dipped during this period. With the enactment of the 1965 Immigration Amendments, immigration increased and by 1970 the city's population rebounded to its 1950 high of 7.9 million.

Figure 2: Total Population, New York City and Boroughs, 1950-2040

Unadjusted decennial census data, 1950-2000; DCP adjusted decennial census data 2010; DCP Population Projections, 2020-2040

The increase in immigration in the 1970s, while substantial, was insufficient to counter the very large domestic outflow. As a result, the city's population declined in the 1970s by more than 10 percent, dropping to 7.1 million in 1980. Lower domestic out-migration in the 1980s, a higher level of immigration, and greater natural increase (much of it related to births among immigrant mothers) all resulted in a return to growth, with the city's population enumerated at 7.3 million in 1990 . With the enumerated population growing by over 9 percent in the 1990s, the city's population officially crossed the 8 million mark in 2000, for the first time.

The basic demographic processes that have defined New York City since the 1950s will likely continue, with sizable outflows from the city offset by immigration and natural increase. Growth between 2010 and 2040 is projected to be lower than the average growth experienced in the 1980-2010 period, but is likely sufficient to propel the city across the 9 million mark by 2040 .

Unadjusted decennial census data, 1950-2000; DCP adjusted decennial census data 2010; DCP Population Projections, 2020-2040

Staten Island, which was the only borough that grew each decade between 1950 and 2010, is projected to have lower growth in the next three decades than any other borough, reaching a new population peak of 501,000 in 2040. As a result, Staten Island, which accounted for 2.4 percent of the city's population in 1950 and 5.7 percent in 2010, is expected to remain in the 5 to 6 percent range in 2040 (Table 8).

Except for a decline in the 1970s, Queens too has increased each decade and will reach a new population peak of 2,413,000 in 2040. Its share of the city's population, which increased from 19.7 percent in 1950 to 27.3 percent in 2010, is expected to be slightly below 27 percent in 2040.

Population growth between 2010 and 2040 in the Bronx is projected at 11.3 percent. Its 2040 projected population of $1,579,000$ will be higher than its 1970 population peak of $1,472,000$ (Table 7). The Bronx's share of the city's population, which was 18.4 percent in 1950 and 16.8 percent in 2010 , is projected to increase again to 17.5 percent in 2040.

Brooklyn's population peaked at 2,738,000 in 1950, and then declined for the next three decades, bottoming out in 1980 at $2,231,000$. Brooklyn has grown each decade since then, but at a relatively modest pace. Its projected 2040 population of $2,841,000$ is above its 1950 population peak. Brooklyn, which comprised 34.7 percent of the city's population in 1950 and 31 percent in 2010, is projected to account for 31.5 percent in 2040.

Manhattan's population peaked in 1910 at 2,332,000, when it constituted nearly one-half of the city's population. It reached a 20th century low of $1,428,000$ in 1980, and its growth in the next two decades was below the city average. By 2010, Manhattan accounted for 19.2 percent of the city's population. Average growth in the next three decades is expected to put Manhattan's population at $1,692,000$ in 2040, when it is projected to be 18.7 percent of the city total.

## School-Age Population, 1950-2040

The size of the school-age population is closely related to the size of birth cohorts. As increasingly large numbers of baby boomers entered school-ages in the post-World War II years, the school-age population increased from 1,259,000 in 1950 to a post-war high of $1,617,000$ in 1970 (Table 9), when school-age children accounted for 20.5 percent of the city's population (Table 10). With the decline in fertility starting in the mid-1960s ("baby bust"), the school-age population declined for the next two decades to just $1,190,000$ in 1990, or 16.3 percent of the total population. By 2000, the school-age population had rebounded to $1,404,000$ or 17.5 percent of the city's population, a result of increases in children of high school-age who were born to baby boomers ("echo effect"). In 2010 the school-age population dropped to $1,260,000$ or 15.3 percent of the city's population, partly a function of a decline in births in the 1990s, which leveled off late in the decade, and have since remained in roughly the same range. The school-age population is projected to increase modestly this decade (2010-2020), but is expected to increase substantially between 2020 and 2030, as anticipated increases in births will once again cause the population of school-age children to rebound to $1,347,000$ in 2030. In the final decade, 2030-2040, the school-age population is projected to decline slightly to $1,342,000$.

The post-war high in school-age population of 1.62 million in 1970 is reflected in each of the city's five boroughs, when they constituted one-quarter of the population of Staten Island, 23 percent of the population of Bronx and Brooklyn, 19 percent of Queens and 16 percent of Manhattan. Notwithstanding the projected growth in the school-age population between 2010 and 2040, the increases in other age groups, especially those 65+, means that the relative share of school-age children in each borough will not even begin to approach the levels seen in 1970. In fact, the share of school-age children in each borough is expected to be below that achieved in 2000, when the city had 1.4 million persons 5 to 17 years of age.

[^0]
## Population 65 Years and Over, 1950-2040

In 1950 the population $65+$ numbered 605,000 , which was just 7.7 percent of the city's population (Tables 11 and 12). The post-war era was characterized by younger mothers, high fertility, and an abundance of young families. Increases in life expectancy in the following decades, combined with declines in fertility after 1964, acted to increase the share of those $65+$ in the overall population. The share increased to 13.5 percent in 1980, and it remained virtually unchanged in 1990. As the small depression-era birth cohorts turned 65+, however, the share of this age cohort dipped to 11.7 percent in 2000. Now as the first of the baby boomer cohorts are beginning to reach the retirement years, the population $65+$ has started to increase again, to 12.2 percent in 2010, with a momentum that will further increase over the coming decades. By 2040, the population $65+$ is expected to grow to $1,410,000$, comprising a 15.6 percent share of the city's population.

Every borough is expected to see the $65+$ population peak by either 2030 or 2040. The relative share of population that persons 65+ constitute will follow suit, with every borough's share no less than twice the 1950s level, and well above their shares in 2000. In Staten Island, which is expected to have the oldest population, persons $65+$ are projected to be one-fifth of the population in 2040, compared with just 8 percent in 1950 and 12 percent in 2000.

Figure 3: New York City Median Age by Borough, 1950-2040

Unadjusted decennial census data, 1950-2000; DCP adjusted decennial census data 2010; DCP Population Projections, 2020-2040

The effect of the growing share of the $65+$ population is reflected in the median age. From 1950 to 1970, the median age fell from 34.5 years to 32.4 years, as the large baby boom cohorts were disproportionately in the youngest age groups (Figure 3). The median age in New York City has increased since then, and is projected at 36.7 years in 2040. Staten Island is projected to have the highest median age in 2040, at 40.3 years, a dramatic change from 1950 when its median age of 31.9 years was the lowest in the city. The median age for Manhattan is projected at 37.6 years, Queens at 37 years, Brooklyn at 36.2 years. The Bronx is projected to be the youngest borough, with a median age of 33.8 years.

## New York City Housing, 1950-2040

The city's overall housing count has increased every decade since 1950 , when there were 2,433,000 housing units, and is projected to rise to $3,696,000$ by 2040. In general, the patterns by borough have been quite distinct, reflecting the economic and housing conditions in each era.

In the 1950s and into the 1960s, despite rising levels of suburbanization, the five boroughs of New York City all saw substantial increases in housing units (Table 13 and Figure 4). Housing units in the Bronx increased by 17.7 percent, from 432,000 to 509,000 . Brooklyn went from 814,000 units to 903,000 , up 10.9 percent; Manhattan from 636,000 to 715,000 units or 12.4 percent. Queens had the largest increase in absolute terms, from 495,000 to 708,000, an addition of 213,000 units, or 43 percent, in just two decades. Finally, Staten Island jumped from 56,000 to 90,000 units ( 61.2 percent), the largest percentage increase among the boroughs. (It is important to keep in mind that the steep changes in Queens and Staten Island reflect their later physical development, relative to the other boroughs of the city.)

Table 13: New York City Housing Units by Borough, 1950-2040

|  | $\underline{1950}$ | $\underline{1960}$ | $\underline{1970}$ | $\underline{1980}$ | $\underline{1990}$ | $\underline{2000}$ | $\underline{2010}$ | $\underline{\underline{2020}}$ | $\underline{2030}$ | $\underline{2040}$ |

[^1]Figure 4: Percent Change in Total Housing Units by Borough, 1950-2040

Unadjusted decennial census data, 1950-2000; DCP adjusted decennial census data 2010; DCP Population Projections, 2020-2040

This picture of rapid growth changed in the 1970s and the early 1980s, when the city's economy faltered. Net losses of housing units were reported in the Bronx (-13.3 percent) and in Brooklyn (-3.2 percent) between 1970 and 1990, with the largest declines occurring in the 1970s. Although Manhattan and Queens showed growth in housing (9.9 and 6.2 percent, respectively), this was lower than in the previous two decades. The only exception was Staten Island, where
growth continued at a very fast pace- 55.3 percent between 1970 and 1990 .
With programs in place to encourage housing development and rehabilitation in the latter part of the 1980s and the 1990s, substantial increases in housing units were evident in several areas of the Bronx, Brooklyn, and northern Manhattan. Thousands of housing units were restored, and with demand for housing up as a result of an uptick in births and higher levels of immigration, many neighborhoods reversed their course of decline. This resulted in housing gains for the Bronx and Brooklyn, with Brooklyn surpassing its 1970 peak in the year 2000. Increases were also apparent in the Bronx, with more than 50,000 additional units added in the 1990s alone. Despite the initial shock of $9 / 11$, the 2000s saw record levels of new construction for several years, boosting housing numbers in all five boroughs. By 2010, the Bronx had recovered fully, with 511,900 housing units, more than its previous peak of 508,800 in 1970. Manhattan and Queens continued to register increases between 1990 and 2010 of 7.9 and 11.5 percent, respectively. Once again, the largest relative increase was in Staten Island, with a jump from 139,700 in 1990 to 176,700 in 2010, an increase of 36,900 or 26.4 percent.

Looking at this short-term history of housing growth along with current land use provides a context for potential housing unit development going forward. This analysis indicates that the Bronx and Brooklyn have the highest potential for continued growth, as reflected in their projected increases between 2010 and 2040. Unlike the Bronx and Brooklyn, Manhattan, Queens, and Staten Island have experienced continuous growth in their housing numbers since 1950. Their high levels of growth are unsustainable given their current patterns of land use.

## Discussion \& Conclusion

In the next three decades, New York City is likely to see lower population growth, compared with the 1980-2010 period, when the city grew by close to 1.2 million persons ( 16.6 percent). Between 2010 and 2040, the city is projected to grow from 8.2 million to slightly over 9 million, an increase of 783,000 , or 9.5 percent. During this 30 year period, the Bronx is expected to grow the fastest ( 14 percent) reaching 1,579,000 in 2040, followed by Brooklyn (11.3 percent) with a 2040 population of $2,841,000$. The other boroughs are projected to have single digit growth, with Queens increasing by 7.2 percent to $2,413,000$, followed by Staten Island ( 6.9 percent) and Manhattan ( 6.7 percent), which are projected to grow to 501,000 and $1,692,000$, respectively, by 2040. For four of the five boroughs, the projected 2040 population represents historical highs. Only Manhattan's 2040 projected population will be far below its historical peak, achieved in 1910, when its population stood at 2.33 million and densities in the populated parts of the borough were more than twice what they are today.

When it comes to a city as large and dynamic as New York, even small changes in underlying socio-demographic assumptions can have a big impact on the numbers three decades into the future. For example, changes in national immigration policies, the economy, and world geo-political events can all affect migration, both domestic and international. A change of just five thousand migrants a year amplified over a 30 year period can have a substantial impact on a population of more than 8 million. When it comes to the age/sex composition of the population, however, the ground is much firmer. With the exception of unforeseeable events, such as large refugee flows, the current age distribution of the population is a good indicator of what the age composition going forward will look like.

The biggest change to come out of this analysis concerns the very large increase in the population 65 years and over, a projected rise of more than 400,000 persons, or 40.7 percent by 2040 . The aging of the large baby boom cohorts, modest growth expected in the number of children, and improvements in life expectancy all contribute to what will be a big demographic shift in the city's age structure. By 2040, every baby boomer will be 75 years or older, and the share of the population that is $65+$ will increase to 15.6 percent citywide, compared with 12.2 percent in 2010. In Staten Island, those $65+$ will account for one-fifth of the population in 2040. Even in the Bronx, the youngest borough on average, 15 percent of the population will be $65+$.

Changes in the school-age population, while far more modest, will still require attention. As the large cohorts of women who are part of the "baby boom echo" (those born in the 1980s) reach their peak reproductive years, levels of childbearing will once again rise, increasing the number of school-age children (ages 5 to 17) later this decade and into the next. All told, the expectation is that there will be 82,000 more school-age children in 2040 compared with 2010, a 6.5 percent rise. This absolute increase is expected to be highest in Brooklyn, with an increase of more than 30,000 school-age children.

The dramatic demographic changes ahead are encapsulated by the changing shares of the school-age and $65+$ populations. As shown in Figure 5, the share of school-age children in 1950 ( 16.0 percent) was more than twice that of the $65+$ population ( 7.7 percent). By 2030, the share of those $65+$ is expected to equal that of school-age children for the first time, with each constituting about 15 percent of the population. By 2040 the share of the population $65+(15.6$ percent) is projected to surpass the share of the school-age population (14.8 percent).

Figure 5: Share of School-age and 65+ Population, New York City, 1950-2040

Unadjusted decennial census data, 1950-2000; DCP adjusted decennial census data 2010; DCP Population Projections, 2020-2040

The implications of a major increase in the population $65+$ are varied and complex, especially with respect to establishing priorities and delivering services. In order to inform decisions, it is useful to examine the size of the population 65+ relative to those in the working ages, which we have set in this analysis as 18 to 64 years. In demography, this is frequently referred to as a measure of "dependency," the implication being that services for those 65+ depend on the economic sustenance provided by those who are economically active. ${ }^{8}$ Figure 6 displays the ratios over time for New York City. In 1950, there were 11 persons $65+$ for every 100 persons in the working ages. This figure increased to a high of 21 in 1980, followed by a decline thereafter. With the aging of the baby boomers, between 2010 and 2040 the ratio of the number of persons $65+$ for every 100 persons in the working ages will increase

Figure 6: New York City Ratio of Persons 65+ to Persons in Working Ages (18-64), 1950-2040

Unadjusted decennial census data, 1950-2000; DCP adjusted decennial census data 2010; DCP Population Projections, 2020-2040 from 18 to 25 . This compares with an increase nationally from 21 to 37 over the same period. New York City's ability to draw young working age migrants-domestic and internationalis a big reason why these ratios are likely to be relatively favorable in the city going forward. ${ }^{9}$

Still, these numbers will likely translate into increased stress on the city's ability to provide services. However, there are several factors that can act to mitigate the impact of these demographic trends, particularly the increased labor force participation of the older population. This phenomenon is partly a result of inadequate savings among many in this group. ${ }^{10}$ The increase in labor force participation could offset some of the costs of providing services to the elderly.

It is important to ask whether these projections portend a new era in New York City's population history, one where each borough reaches the carrying capacity of its infrastructure and available land for residential development. New York City has been a core area of growth for the Metropolitan Region since 1980, being responsible for a sizable share of the increase in the region's population and housing. To enable population growth in the region to support economic expansion in the long-term, other urban centers in the region with the capacity to support population increases will need to take the necessary measures to achieve greater density, easing the pressure on New York City as an engine of growth.

Finally, the cohort-component model creates a projection based on a set of assumptions about fertility, mortality and migration, using data from the city's recent past. While the rates of fertility and mortality tend to change slowly over time, as noted earlier, migration rates can vary substantially. More importantly, because the city's population is so large, small deviations in assumed rates can have large effects on the city's population going forward. And, like the demographic model, the planning component, which helps determine migration rates, is subject to re-evaluation over time as a result of changes in land use and zoning. These limitations notwithstanding, this analysis provides a useful tool for those who need to plan for the city's future.

## Adjusting for the Census Undercount: Effect on Population Growth and Components of Population Change, 1950-2040

This report uses population data by age and sex that were enumerated in prior decennial censuses. However, a more accurate picture of the magnitude of the city's growth and the components of its population change can be gained by using data from the Census Bureau that are adjusted for the undercount.

## Methods and Sources

Evaluation of census coverage (or "undercount") is generally done through the creation of independent estimates of population that can be compared to results from the decennial census. Post-enumeration surveys or estimates derived from demographic analysis (i.e., changes in births, deaths, and migration since the previous census) are the main methods used to construct independent estimates of population. For 1970 through 2010, estimates derived from at least one of these methods were used to evaluate the level of undercount. For 1970, the estimate was restricted to the black population, since other groups were not separately identified; for 1980, an estimate of undercount applied to statewide projections was obtained from the New York State Data Center; in 1990, the Census Bureau's Post-Enumeration Survey (PES) results were used to adjust the population; and in 2000, the Census Bureau's Accuracy and Coverage Evaluation (ACE) results were utilized. Although the results of the Census Bureau's Census Coverage Measurement (CCM) Program for 2010 did not reveal a statistically significant undercount of the population, ${ }^{1}$ local administrative data confirmed the existence of an anomaly in the census that was largely restricted to several areas of Brooklyn and Queens. ${ }^{2}$ This undercount was partly due to an erroneous increase in vacant units, so an adjustment was implemented to compensate for this undercount. ${ }^{3}$

## Results

Adjusted data, which are available for the overall population of New York and generally not by age/sex, show that the city's adjusted population was slightly over 8 million in 1970, 7.2 million in 1980, 7.6 million in 1990, over 8 million in 2000 , and 8.2 million in 2010 (See table 14 below).

Using adjusted data, Figure 7 shows population change by decade, which is a result of two basic demographic components: natural increase (the balance of births and deaths) and net migration (the balance of persons entering and leaving the city). New York's population grew each decade in the first half of the 20th century reaching a new high of 7.9 million in 1950. Thanks to high baby boom fertility, natural increase totaled 747,000 in the 1950s, but net migration losses

[^2]of 857,000 led to the population declining to 7.8 million in 1960 . Net migration losses fell to 338,000 in the 1960 s and the population increased by 256,000 to an adjusted 1970 total of over 8 million. The decade of the 1970s was marked by a large net migration loss of 1.15 million, and thanks to the baby bust, natural increase of only 339,000 , leading to a population decline of 806,000 . With domestic outflows moderating in the 1980 s, net migration losses fell to 72,000 and the city grew by 336,000 , to an adjusted population of 7.6 million in 1990. Net migration losses were just over 100,000 in the 1990s, while natural increase stood at 584,000 , resulting in an adjusted population gain of 477,000 . This pattern continued in the first decade of the 21 st century, with net migration losses of 472,000 offset by gains of 639,000 through natural increase - the resulting growth of 234,000 put the city's adjusted population at 8.24 million in 2010.

The city is expected to continue to experience net migration outflows in the post-2010 period. Between 2010 and 2020, net migration losses are projected to be 387,000 and will be around 400,000 in the subsequent two decades. These net losses mask huge underlying inflows and outflows, a testament to the continued dynamic nature of the city's population. Despite these losses through net migration, the city will continue to grow due to natural increase, projected at 690,000 in 2010-2020, declining to 674,000 in the subsequent decade, and to 619,000 in 2030-2040. Thus the basic process of population change is projected to stay in place in the post-2010 era, with the city's population shaped by continued net out-migration, offset by natural increase.

Table 14: Enumerated and Adjusted Census Populations, 1970-2010

|  | Enumerated | Adjusted |
| ---: | ---: | ---: |
| 1970 | $7,894,862$ | $8,038,121$ |
| 1980 | $7,071,559$ | $7,231,639$ |
| 1990 | $7,322,654$ | $7,567,146$ |
| 2000 | $8,008,278$ | $8,044,075$ |
| 2010 | $8,175,133$ | $8,242,624$ |

## ENDNOTES

1. For more information, see: http://www.nyc.gov/population.
2. For more information, see: http://www.nyc.gov/html/planyc2030/html/publications/publications.shtml.
3. Base refers to the population that is used at the start of the projection model. In this particular case, the "base" population used is the DCP adjusted 2010 decennial census count.
4. The 2010 Census population in Brooklyn and Queens was adjusted due to erroneous vacancies and deleted units in southern Brooklyn and northwest Queens. This resulted in an increase in the population of Brooklyn from 2,504,700 to 2,552,911. In Queens, the population rose from 2,230,722 to 2,250,002. The additional population brought New York City's total population in 2010 from 8,175,133 up to 8,242,624. See Appendix I for more information.
5. Although survival was adjusted for all ages, the largest improvements are in the oldest age groups.
6. For more information, see Salvo, J.J. and A.P. Lobo (2013). "Misclassifying New York's Hidden Units as Vacant in 2010: Lessons Gleaned for the 2020 Census." Population Research and Policy Review, 32(5), 729-751.
7. The census challenge is available at: http://www.nyc.gov/html/dcp/html/census/census_challenge_2010.shtml.
8. In the coming years, the word "dependency" may become a misnomer, given likely increases in labor force participation among those 65 years and over.
9. The 2010 ratios for some counties known as bastions for older populations are as follows: Palm Beach Florida - 37; Ocean New Jersey 36; Pima Arizona - 25.
10. See Leonesio, M. V., B. Bridges, R.Gesumaria, and L.Del Bene (2012). "The Increasing Labor Force Participation of Older Workers and its Effect on the Income of the Aged." Social Security Bulletin, Vol. 72, No. 1.

## APPENDIX I: METHODOLOGY

## Introduction

The objective of this analysis was to produce population projections by age and sex, at 5 year intervals from 2010 through 2040 for each of New York City's five boroughs. The projections were created using a cohort component model. This model is based on the premise that population growth can be broken down into three main components: births, deaths, and migration. While births increase the base population and deaths reduce it, migration results in an addition or diminution depending on whether there is overall positive or negative migration. Therefore:

## Projected Population $\left(\mathbf{P}_{1}\right)=$ Base Population $\left(\mathbf{P}_{\mathbf{0}}\right)+$ Births - Deaths + Net Migration

The power of the cohort component model is based on its use of age and sex cohorts ${ }^{1}$ as a starting point. Births, deaths, and migrants are then used to move these cohorts forward through time, creating a new age/sex distribution at each five year time point. A particular cohort's ability to grow or decline is dependent on the impact these components have on each age and sex group. It is essentially an "accounting approach" to modeling population changes-one that applies birth, death, and migration rates to these age and sex cohorts.

The fundamental difficulty in using the cohort component model rests in identifying appropriate fertility, mortality, and migration rates to apply to different age groups. In general, most baseline projections assume that the future will be in line with historical patterns. These baseline assumptions are then modified using scenarios that demographers believe may be likely in the future. For example, one may increase survival rates based on a forecasted increase in longevity. Similarly, knowledge of new housing development may spur a planner to lower net migration losses going forward, keeping more people in a jurisdiction over time. Of course, the degree to which such future patterns hold is directly related to the ultimate success of a projection. For these projections, migration rates were closely analyzed to ensure that the resulting projection of population and housing could be reasonably accommodated, given the city's current land use and zoning. This model is thus sensitive to the opportunities and constraints related to changes in each borough's land use, zoning, and the production of housing.

There were four distinct stages in the creation of these projections:
I. Adjusting the 2010 census population in Brooklyn and Queens and removing the group quarters population;
II. Creating the baseline - building a series of fertility, mortality and migration rates by age/sex;
III. Creating 2015 and 2020 populations from projected housing permits and certificates of occupancy;
IV. Adjusting the projection for five year time points by age/sex, for 2020 to 2040.

# I. Adjusting the 2010 Census Population in Brooklyn and Queens and Removing the Group Quarters Population 

## Adjusting the 2010 Census Population in Brooklyn and Queens

Reasonable estimates of population change can only be obtained when errors in census coverage (also known as "undercount") are relatively constant from one census time point to the next. Therefore, before assessing change from 2000 to 2010, an evaluation of undercount for both time points was conducted.

The undercount in 2000 was negligible, but New York City's population as of April 1, 2010, reported as $8,175,000$, was well under estimates prepared by New York City Department of City Planning (DCP) in cooperation with the Census Bureau. This undercount was partly due to the 2010 Census reporting an increase of 82,000 vacant units in New York City, a 46 percent rise since 2000. A disproportionate share of this increase was found in two local census offices (LCOs) covering southern Brooklyn and northwest Queens, both vibrant sections of the city with substantial housing demand. The huge concentration of vacant units in these areas cannot be explained by new construction or foreclosures; nor is it consistent with other survey and administrative data. ${ }^{2}$ As a result, an adjustment to the population in Brooklyn and Queens was employed to compensate for this undercount.

The 2008 New York City Housing and Vacancy Survey (HVS), the standard for measurement of vacancy, was used to estimate the true number of vacant units in Brooklyn and Queens. There was also an issue of units that were erroneously deleted in Queens. The 2010 DCP estimate of total housing units was compared to the 2010 Census count to determine the number of deleted units. The population that was added to these boroughs was calculated by applying an average household size to the number of additional units in Brooklyn and Queens.

The DCP estimates of the population missed due to erroneous vacancies in Brooklyn and vacancies and deleted units in Queens, added 48,211 people to the total population in Brooklyn and 19,280 people to Queens. This increased the population of Brooklyn from 2,504,700 to 2,552,911. In Queens, the population rose from 2,230,722 to 2,250,002. The additional population brought New York City's total population in 2010 from 8,175,133 up to 8,242,624. ${ }^{3}$

## Removing the Group Quarters Population

When considering those who live in a dormitory, nursing home, correctional facility or other places where the population is supervised and not living in housing units - defined as "group quarters" - their mortality, fertility, and migration patterns are different from those living in households. Therefore, the group quarters population was initially removed from the general population and then placed back in after the projection was completed. Thus, the group quarters population remained the same from base year to the final projection year. ${ }^{4}$

## II. Creating the Baseline

This section examines how the three components of population change were calculated and how they were employed in the projection model.

## Fertility

So as not to be subject to any one-year anomaly, births were averaged for 2008, 2009, 2010, and age-specific rates were calculated based on the 2010 population. ${ }^{5}$ Birth data were obtained from the New York City Department of Health and Mental Hygiene, while population data by age were from the decennial census. The age-specific fertility rates determine how births are distributed by age of the mother. Unlike a conventional age pattern of fertility, where child-bearing occurs primarily in the younger age groups, New York City sees a disproportionate number of births to older women.

Appendix Figure 1: Age-Specific Fertility Rates by Borough, 2010

Rates rose at ages 20-24, continued to increase until 30-34, and then fell steeply thereafter (Appendix Figure 1). The two boroughs that had the highest overall fertility, the Bronx and Brooklyn, also had the highest age-specific fertility rates for those ages 20-24. Alternatively, Queens and Staten Island followed a more "suburban" fertility pattern, with moderate overall levels, and rates peaking at ages 30-34 for both boroughs. Manhattan had remarkably low overall fertility, especially for those under age
30. Unlike other boroughs, women in Manhattan ages 35 to 39 had fertility rates higher than for those in their 20s, usually the prime child-bearing ages.

Since the baby boom ended in the 1960s, New York City has experienced a fairly steady decline in fertility rates that has continued to fall through the 2000s. Given these low fertility rates and the difficulties inherent in projecting fertility, 2008-2010 fertility rates were held constant for the entire 2010-2040 period. Since the aggregate number of births is the result of both fertility rates and the number of women in the childbearing ages, the number of births may increase in some years, despite unchanging or even declining fertility rates. ${ }^{6}$

## Mortality

As with births, deaths were averaged for 2008, 2009, and 2010 to calculate age-specific death rates based on the 2010 population. Data on deaths were obtained from the New York City Department of Health and Mental Hygiene, while population data by age were obtained from the decennial census. These age-specific death rates were then used as the foundation for a life table that calculated survival rates by age. These rates represent the percentage of persons who are likely to survive to the next five year time point. ${ }^{7}$ While younger age groups have much higher survival rates than older ones, but no age group is immune from death over a five year period.

us to project the population by age and sex.

The initial survival rates, which were employed for the 2010-2020 period, follow a very traditional pattern of high probability of survival for the younger ages, with very little attrition until ages 55-59 (Appendix Figure 2). Thereafter, the probability of survival begins to fall, declining steeply for the older age groups. Survival rates in the Bronx were minimally lower than those for other boroughs. While our focus is on age-specific survival rates, the cohort component model used in this analysis actually uses rates that are age- and sex-specific. This permitted

Starting in 2020-2025, survival was increased for each group by applying age-specific improvements anticipated by The United States Social Security Administration. The ratio of increase in survival for the United States was applied to each borough. Given the fact that the city's life expectancy in 2010 already exceeded the national average, it was unrealistic to assume that New York City's experience would continue upward at the same rate as the nation. Therefore, just $50 \%$ of the difference between the boroughs and the national survival rate was added to the borough's rate. This method was repeated at each 10 year time point, while holding the 5 year period in between constant with the decade's survival rates.

## Migration

Since migration is the most volatile component, age-specific and crude migration rates (CMRs) were calculated using decennial census data from 1990-2000 ${ }^{8}$ and 2000-2010.

For all but the youngest age groups, net migration is derived as a residual by applying mortality rates and "surviving" an enumerated population, yielding an "expected" population for each age/sex group five or ten years later. For example, some number of 45-49 year olds in 2000 will survive to ages 55-59 in 2010. This expected population of 55-59 year olds is then compared to the observed or actual population of 55-59 year olds in the 2010 census; the difference, or residual, is net migration. Net migrants were divided by the initial population to create age-specific migration rates for each 5 year period and then averaged to arrive at the rate for the entire decade. ${ }^{9}$ Like all measures, however, this calculation is subject to error. Since the reporting of deaths by age/sex is largely complete in New York City, most of the error is likely related to coverage - undercount or overcount - of the population in 2000 or 2010.

It can be very difficult to detect the impact of coverage errors. The Census Bureau evaluates coverage after every census, but rarely are estimates provided in a form that is useful for performing population adjustments. Given the recognition of substantial undercount in the 1990 Census, the Census Bureau did provide some estimates by age/sex that
were applied in these projections. With some exceptions (see earlier discussion), the systematic undercount problems identified in 1990 were likely not present in the 2000 or 2010 Censuses. Still, all censuses contain errors of coverage and it is prudent to be aware of this when analyzing the rates that form the foundation of these projections.

Since it is calculated as a residual, any estimate of net migration will include errors associated with population coverage. This can manifest itself in the form of unusual changes in net migration rates among successive age/sex groups. In Brooklyn and Queens, volatility was observed in net migration rates among persons between the ages of 45 and 60 , which was characterized by big shifts in the direction of rates for successive age groups. As a result, age cohorts that historically had net outflows and declined as they moved across the age spectrum were now erroneously seeing net inflows and were increasing in size as they aged. These effects were dampened by averaging the rates for adjacent age groups. This has the effect of smoothing rates in the middle/upper ages, making for a scenario that was likely less sensitive to anomalies in the coverage of age/sex groups in the census enumeration.

Appendix Figure 3: Age-Specific Migration Rates by Borough, 1990-2010

With the exception of a small inflow for ages 15-29, the Bronx had negative migration for all of its age groups (Appendix Figure 3). The rates in Brooklyn and Queens for the young age groups were more than twice that of the Bronx. In comparison, Manhattan had an extraordinarily positive net migration rate for those 20-29. Manhattan also had among the highest rates of out-migration for most age groups thereafter. Staten Island, unlike the other boroughs, had positive migration rates for a majority of its age groups, especially those groups of people younger than 55 years old. In all of the boroughs, migration rates in the older age groups showed greater out-migration than in the younger age groups.

While overall rates of migration vary by borough, there are age-specific patterns that hold across boroughs. For example, with the exception of Staten Island, all boroughs have a net outflow for those under the age of 5, as new parents often leave for the suburbs to raise their children. In contrast, migration rates are positive for those ages 20-29 in each borough. Among those ages 30 to 54 , migration rates tend to be close to zero, with the notable exception of Manhattan, which has a sizable outflow, especially for those ages $30-49$. For those ages 55 to 89 , migration rates are negative for all boroughs. ${ }^{10}$

The overall migration dynamic is captured by the CMR, which was calculated by totaling net migrants in each 5 year period and dividing that by the mid-decade population. ${ }^{11}$ A positive CMR means that those who move into the city outnumber those who leave, while the reverse is true if the rate is negative. Migration trends for New York City from 1990-2010 are slightly negative overall, but vary by borough. The Bronx, Brooklyn, and Manhattan all had negative CMRs. While Queens also had a negative overall rate, it was not to the same degree as the other boroughs. Staten Island was the only borough to have a positive CMR.

## III. Creating 2015 and 2020 populations from projected housing permits and certificates of occupancy

Appendix Figure 4 shows the methodology that was used to create a projected 2020 population. The approach takes advantage of the fact that actual population and housing data exist for part of the 2010-2020 period. A 2020 housing target was created that used three inputs: 1) Certificates of Occupancy (C of Os) for 2010 to 2013; ${ }^{12}$ 2) demolitions for the years 2005 to 2012; and 3) the average number of building permits issued between 2005 and 2012, which was used as the estimated number of building permits for each of the years between 2014 to 2020. Permits issued between 2005 and 2012 were examined and a net number was created by subtracting the demolitions from the permits for each year. For each year, C of Os that were tied to the permits issued in each of the above years were tracked, resulting in a determination of units that were completed and occupied. ${ }^{13}$ An annual rate of completion/occupancy was applied to the estimated number of building permits for 2014-2020, to obtain the estimated number of C of Os for each of these years. The actual number of C of Os for 2010 to 2013 was then summed, along with the projected number of completions for 2014 to 2020, to obtain the number of housing units for the 2010-2020 period.

Appendix Figure 4: Methodology for 2020 Population Projection

The housing number was then converted into population by using the average household size and occupancy rates for each borough. The baseline CMRs were adjusted for 2010 to 2020 in order to bring the cohort-component population projection for each of the boroughs in line with the population based on the 2020 housing target. ${ }^{14}$

## IV. Adjusting the projection for five year time points by age/sex for 2020 to 2040

Appendix Figure 5 shows the methodology that was used to create the 2040 population projection. This approach uses the cohort-component projection to create a population and housing number for 2040 and then evaluates that number against the opportunities and constraints related to changes in each borough's land use, zoning, and the production of housing. This is referred to as the planning component, or a check of the reasonability of the demographic model
to ensure that the demographic projections can be accommodated by the city's housing. In general, it is this planning component that may dampen the tendency for demographic projections to show linear increases as the lack of capacity for new residential development acts to constrain growth.

The planning component, done with local knowledge of each borough, consisted of five categories of opportunities for future growth.

1. DCP initiatives/re-zonings: up-zoning areas for increased housing opportunity
2. Large private applications: large private developments that generate new housing
3. Large public site projects: NYCHA, HPD, and city-owned sites
4. Opportunity areas: increased housing along major corridors and thoroughfares
5. Background growth ${ }^{15}$ : soft site analysis and underutilized areas

The analysis also looked at constraints in the boroughs that could prevent growth from occurring.

1. Carrying capacity of the infrastructure: existing water supply and sewer capacity
2. Land development needs of public facilities: including schools, parks, libraries, police, and fire departments
3. Non-residential uses: prohibits residential development

Appendix Figure 5: Methodology for 2040 Population Projection

Each development or opportunity identified in the planning component was accompanied by the projected number of housing units that could be built when the development will be completed. The number of housing units was then summed for each borough and, using current occupancy rates and average household size, a population associated with the projected number of housing units in 2040 was derived. The CMRs were then adjusted for the period between 2020 and 2040 to ensure that the projected population could be accommodated given the prospective housing potential in each borough. The CMRs in the Bronx and Brooklyn were changed to reduce migration losses, while the reverse was true in Manhattan, Queens, and Staten Island. In general, the results show that each borough is projected to increase its population, but at a decreasing rate.

## ENDNOTES

1. A cohort is a group of people sharing the same demographic characteristics, in this case age and sex (e.g. 30-34 year old males). Those in the same cohort are subject to the same components, and will move through the projection together.
2. See Salvo, J.J. and A.P. Lobo (2013). "Misclassifying New York's Hidden Units as Vacant in 2010: Lessons Gleaned for the 2020 Census." Population Research and Policy Review, August.
3. Erroneous vacant units in Brooklyn were estimated at 18,090 , which accounted for an estimated population of 48,211 . In Queens, erroneous vacancies were estimated at 3,278 , resulting in 8,160 persons added. In addition, Queens had an estimated 3,940 erroneously deleted units, resulting in an added population of 11,120, for a total population added in Queens of 19,280.

More information is available at: http://www.nyc.gov/html/dcp/html/census/census_challenge_2010.shtml.
4. Increases in group quarters populations are often projected when there are plans to expand or create new group facilities. Given the difficulty of projecting such plans, the population in group quarters was held constant over the projection period. The group quarters population in the 2010 Census stood at 185,500 , slightly higher than the 182,400 persons enumerated in the 2000 Census.
5. Age-specific fertility rates are based on five year age groups beginning with 15-19 year olds and ending with 45-49 year olds. All these age groups represent the "child-bearing" population. In order to calculate the actual rates, the number of births an age group produced is divided by that age group's female population. For this projection, births were based on a three year average (2008, 2009, and 2010) so that the yearly estimate of births is not subject to any one-year anomalies. All the age-specific fertility rates are multiplied by five to obtain a rate for the five year projection interval.

These age-specific rates can be summed to produce an overall measure of fertility for women in each borough, called the Total Fertility Rate (TFR). Adjusting the TFR permits us to change overall rates for women in all age groups (moving them up or down, but maintaining the overall pattern by age), while adjustments to the age-specific fertility rates permit us to alter fertility levels for particular age groups.
6. For example, despite the post baby boom decline in rates, births did increase in the 1980s and peaked in 1990 at 135,000 . This was still well below the level achieved in 1961, when the number of births exceeded 168,000.
7. Survival rates are not precisely the proportion surviving to the next age group. Instead, they are calculated through a life table, which determines survival in terms of life expectancy and person years lived within an interval against all remaining intervals. This is because each age group is not subject to the exact same chances of dying, since people are distributed evenly throughout the age group. For instance, the $0-4$ year old age group is not merely comprised of infants at the beginning of the projection. Rather, it includes infants, $1,2,3$, and 4 year olds alike. This is why a simple proportion cannot be applied to each age group -- people are moving to the next age group before the five year period has concluded and are thus subject to a different probability of dying.
8. For 1990-2000, an adjusted population was used for 1990 and the Census population was used for 2000. The undercount for 1990 was high, compared to a negligible number for 2000. The age/sex distribution of the undercounted population in New York City was not available. At the national level, undercount rates by age/sex were available through demographic analysis, so this distribution was used to make adjustments to the city's population in 1990.
9. For each decade, migration rates were calculated for a 5 year period and then averaged to create the rate for the entire decade. The rates for 1990-2000 and 2000-2010 were then averaged to create a rate for the entire 1990-2010 period.
10. Males and females in each borough tend to have similar patterns of migration, differing only in terms of magnitude. While this section focused on age-specific patterns of migration, age/sex-specific migration rates were used for the migration component. This allows us to project population by sex.
11. The crude migration rate (CMR) is calculated by adding the estimated number of net migrants in the first portion of the relevant historical period to the net migrants in the second portion of the period, dividing by 2 , then dividing that figure by the mid year population of the same period. For example, to obtain the CMR for 1990-2000, 1990-1995 net migrants would be added to the 1995-2000 net migrants, then divided by two, then divided once again by the 1995 population. A rate for 2000-2010 would be calculated in a similar manner and the rates for the two decades would then be averaged.

While the age-structure of migration can be altered by changing age-specific rates, adjusting the overall CMR changes migration rates across all age groups while maintaining the overall pattern of migration by age.
12. For 2013, data were available for only the first six months; this figure was doubled to obtain the total for the entire year.
13. For permits issued in a given year, it takes an average of six years for them to be built and occupied.
14. The following CMR borough rates (in thousands) for males and females refer to the baseline and the 2010-2020 adjustment:

|  | Males |  |  | Females |  |  |
| :--- | ---: | ---: | :--- | ---: | ---: | ---: |
|  | $\underline{\text { Baseline }}$ | $\underline{2010-2020}$ |  | $\underline{\text { Baseline }}$ | $\underline{2010-2020}$ |  |
| Bronx | -42 | -42 |  | Bronx | -26 | -22 |
| Brooklyn | -40 | -40 |  | Brooklyn | -26 | -24 |
| Manhattan | -35 | -35 |  | Manhattan | -18 | -11 |
| Queens | -11 | -11 |  | Queens | -6 | -12 |
| Staten Island | 14 | 14 |  | Staten Island | 21 | -2 |

While it was possible to change the age-structure of migration by altering age-specific rates, no such changes were made in this projection, but for the initial changes in 2010 in Brooklyn and Queens, since age patterns of migration tend to be stable over time. Instead, the overall CMR was adjusted, which changes migration across all age groups, but maintains the age-specific migration patterns.
15. Excluded from background growth are lots that are built over $50 \%$ of its maximum capacity under current zoning. In addition, lots less than $2,500 \mathrm{sq} \mathrm{ft}$, publically own land, lots with rent stabilized buildings, landmark buildings, historical districts, parkland and cemeteries, were all excluded from the background growth analysis. Also, in the case of Brooklyn and Queens, one and two family homes were removed, since many one and two family homes are owner-occupied and located in low-density areas, it is unlikely that these homes will be redeveloped into larger buildings with more units.
16. It is important to note that estimating a housing unit increase is not an exact science, but an approximation of the number of housing units that may be created as a result of a borough's current land use and zoning.
17. The following CMR borough rates (in thousands) for males and females refer to the baseline, the 2010-2020 adjustment, and the 2020-2040 adjustment:

|  | Males |  |  |  | Females |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Baseline | 2010-2020 | 2020-2040 |  | Baseline | 2010-2020 | 2020-2040 |
| Bronx | -42 | -42 | -28 | Bronx | -26 | -22 | -18 |
| Brooklyn | -40 | -40 | -29 | Brooklyn | -26 | -24 | -19 |
| Manhattan | -35 | -35 | -25 | Manhattan | -18 | -11 | -13 |
| Queens | -11 | -11 | -35 | Queens | -6 | -12 | -19 |
| Staten Island | 14 | 14 | -5 | Staten Island | 21 | -2 | -8 |

## Appendix II: Detailed Projection Tables by Age/Sex \& Borough, 2010-2040

## How to Read the Tables

The following tables present age distributions for New York City and each borough for six intervals, from 2010 to 2040. Reading left to right, the color of each cell indicates the percent change in population from 2010 to the period specified at the top of each column. As indicated in the legend, red cells display declines in the number of persons compared with 2010, and the blue colored cells indicate increases, with white cells displaying negligible changes. For example, in New York City, the number of persons aged 40-44 in 2025 is projected to increase by 6 percent (light blue) over the number of $40-44$ year olds in 2010 (from 571,825 to 606,185 persons).

The experience of age cohorts (persons born over a specified period) can be followed on each diagonal. This means that any changes in the number of persons along each diagonal are not due to changes in the size of birth cohorts, but to the effects of aging and/or migration. For example, the age cohort of $40-44$ year olds in 2010 diminishes as we move along the diagonal, from 571,825 (2010), to 535,998 (2015), to 520,597 (2020), to 474,319 (2025), to 447,688 when this group is $60-64$ in 2030. Deaths among members of the age cohort and net migration losses account for the lower numbers as we move forward in time.

Appendix Table 1
Population Projections for Total Population by Age
New York City, 2010-2040

| Age | 2010 | 2015 | 2020 | 2025 | 2030 | 2035 | 2040 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0-4 | 521,990 | 535,209 | 545,778 | 547,336 | 542,426 | 540,523 | 546,426 |
| 5-9 | 477,039 | 501,640 | 516,006 | 527,690 | 529,397 | 524,170 | 522,152 |
| 10-14 | 471,909 | 457,567 | 482,453 | 497,610 | 508,958 | 509,963 | 504,650 |
| 15-19 | 539,844 | 505,783 | 492,532 | 519,298 | 535,024 | 546,062 | 546,750 |
| 20-24 | 647,483 | 646,075 | 606,203 | 591,683 | 625,253 | 643,728 | 657,403 |
| 25-29 | 736,105 | 770,396 | 763,956 | 715,824 | 698,195 | 740,437 | 762,757 |
| 30-34 | 667,657 | 707,726 | 743,916 | 740,268 | 693,684 | 675,497 | 715,486 |
| 35-39 | 592,299 | 611,239 | 649,594 | 684,249 | 682,964 | 639,237 | 621,899 |
| 40-44 | 571,825 | 550,097 | 569,628 | 606,185 | 638,148 | 637,517 | 596,493 |
| 45-49 | 570,273 | 535,998 | 517,668 | 537,516 | 571,723 | 600,792 | 600,514 |
| 50-54 | 546,204 | 552,074 | 520,597 | 504,322 | 523,815 | 556,586 | 584,164 |
| 55-59 | 479,661 | 493,997 | 501,239 | 474,319 | 459,574 | 477,052 | 506,390 |
| 60-64 | 418,127 | 449,279 | 464,187 | 472,842 | 447,688 | 434,046 | 450,353 |
| 65-69 | 299,533 | 353,131 | 380,864 | 395,585 | 403,234 | 382,256 | 370,119 |
| 70-74 | 236,401 | 256,786 | 304,072 | 330,132 | 342,704 | 350,069 | 331,544 |
| 75-79 | 179,677 | 192,687 | 210,236 | 251,182 | 272,561 | 284,051 | 289,778 |

[^1]:    Unadjusted decennial census data, 1950-2000; DCP adjusted decennial census data 2010; DCP Population Projections, 2020-2040

[^2]:    1 The Census Bureau 2010 CCM results actually showed a net overcount for New York City, but the results were not statistically significant. See U.S. Census Bureau, Census Coverage Measurement Summary Results for New York: http://www.census.gov/coverage_measurement/ post-enumeration_surveys/stateinfo36.html.

    2 For more information, see Salvo, J.J. and A.P. Lobo (2013). "Misclassifying New York's Hidden Units as Vacant in 2010: Lessons Gleaned for the 2020 Census." Population Research and Policy Review, 32(5), 729-751.

    3 Erroneous vacant units in Brooklyn were estimated at 18,090, which accounted for an estimated population of 48,211. In Queens, erroneous vacancies were estimated at 3,278 , resulting in 8,160 persons added. In addition, Queens had an estimated 3,940 erroneously deleted units, resulting in an added population of 11,120 , for a total population added in Queens of 19,280 . More information is available at: http://www.nyc. gov/html/dcp/html/census/census_challenge_2010.shtml.
