6.13 VIBRATION

6.13.1 Introduction

Construction activities have the potential to produce vibration levels that may be annoying or disturbing to humans and may cause damage to structures. Architectural and even structural damage to existing structures surrounding a site could occur if appropriate precautions are not taken.

The effects of ground-borne vibration include discernable movement of building floors, rattling of windows, shaking of items on shelves or hanging on walls, and rumbling sounds. The vibration from the construction-related activity “excites” the adjacent ground, creating vibration waves that propagate through the various soil and rock strata to the foundations of nearby buildings. As the vibration propagates from the foundation through the remaining building structure, certain resonant, or natural, frequencies of various components of the building may be excited. In extreme cases, vibration can cause damage to buildings.

This Section discusses existing vibration conditions in the vicinity of the Shaft Site and assesses the potential for construction at the E. 59th Street/Second Avenue Shaft Site to result in vibration impacts. The methodology used to prepare this Section is described in Section 3.12, “Vibration,” in Chapter 3, “Impact Methodologies.”

In addition to the Shaft Site itself, this alternative would involve construction of a water main connections. The water mains could travel one block within E. 59th Street from the Shaft Site to First Avenue where they would coincide with the potential First Avenue or Sutton Place water main routes discussed in Chapter 5, “Water Main Connections.” These activities would be short-term and temporary in nature. Therefore, no potential significant adverse vibration impacts would be anticipated to occur from water main construction.

6.13.2 Existing Conditions

As discussed in Section 4.13, “Vibration,” in Chapter 4, “Preferred Shaft Site,” an ambient vibration survey was conducted to establish the baseline vibration levels from traffic traveling over the Queensboro Bridge to determine whether there would be cumulative vibration effects with the shaft construction activities. The results of the vibration monitoring show that existing vibration levels are negligible and would not affect the impact criteria for structural damage or procedures for the shaft construction activities.

6.13.3 Future Conditions Without the Project

None of the projects identified for development between 2006 and 2012 would be expected to introduce significant vibration levels in the Study Area. Therefore, vibration levels would be
expected to be comparable to those currently existing in the vicinity of the E. 59th Street/Second Avenue Shaft Site.

6.13.4 Future Conditions With the Project

Construction

Overview

Controlled blasting, pavement breaking (including jack hammers), rock drilling, soil compaction, and pile installation would produce the highest vibration levels during construction of this alternative Shaft Site. Blasting is discussed first, followed by a discussion of other construction activities at this Site.

Protective measures will be implemented to avoid potential construction-related vibration impacts at the Shaft Site. Additional protection measures will be put in place to protect fragile, sensitive, and historic structures. At the E. 59th Street/Second Avenue Shaft Site, the Queensboro Bridge is the only known or potential historic resource within 100 feet of this site.

A detailed vibration control plan that will include the measures discussed below will be developed by the construction contractor prior to construction. The plan will include a vibration monitoring program to be implemented during construction. The detailed vibration plan will account for specific geological conditions, foundation assessment of structures near vibration-causing construction activities, and the appropriateness of the vibration thresholds to affected buildings. Finally, the detailed plan will include specific measures and best management practices to avoid potential vibration impacts.

In advance of certain activities that are likely to result in high vibration levels such as blasting, NYCDEP and its contractors would conduct extensive outreach to those in the vicinity of the Shaft Site that could be affected. This would include providing the nearby community with the expected start date for blasting operations, the general time pattern during the ensuing months, and the timing and significance of the warning whistles.

Finally, NYCDEP would not permit construction activities to occur between 11:00 p.m. and 7:00 a.m. with the exception of the raise boring activities that would occur for 3 months for 24 hours per day, 7 days per week. Blasting operations would be expected to occur during daytime hours or as prescribed by the FDNY (see Section 4.13, “Vibration,” in Chapter 4, “Preferred Shaft Site”).

Blasting

Of the construction activities proposed, blasting would result in the highest potential vibration levels. Blasting would be necessary at this Shaft Site to enlarge the shaft and form the distribution chamber at the top of the shaft. Blasting would not occur at the ground surface since the bedrock at the site is more than 15 feet below the ground surface. As described in Section 6.1, depending on the construction schedule for the project at this site, different construction techniques (either the raise bore method or the surface excavation method) would need to be
utilized for shaft construction. Like the preferred Shaft Site, blasting would be expected to occur for roughly eight months using the raise bore method. Under the surface excavation method, blasting would occur over a 24-month period (18 months for the shaft and 6 months for the distribution chamber). While the time period is longer for the surface excavation method, there would be one, rather than two, blasts per day for the shaft work and two per day for the distribution chamber work (as with the raise bore method).

Section 4.13, “Vibration,” in Chapter 4, “Preferred Shaft Site,” discusses blasting procedures, including protective measures that will be implemented to avoid potential construction-related vibration impacts from blasting at the preferred Shaft Site. There is also a discussion of special protection measures that will be put in place to protect fragile, sensitive, and historic structures. These same procedures would be put in place at the E. 59th Street/Second Avenue Shaft Site due to its close proximity to the Queensboro Bridge.

Other Construction Activities

Other construction activities would result in varying degrees of ground-borne vibration, depending on the stage of construction, the equipment and construction methods employed, the distance from the construction to vibration-sensitive receptors and geotechnical and soil conditions. The following activities and equipment could induce the highest vibration levels:

- Raise boring from the tunnel upwards with rotary drilling equipment.
- Soil compaction with a compactor.
- Pile installation with a pile drill rig.
- Rock drilling with crawlers or pneumatic hammers.
- Pavement breaking with jackhammers.
- Delivery and cement trucks.

The use and potential vibration effects of this equipment are discussed in Section 4.13, “Vibration,” in Chapter 4, “Preferred Shaft Site.” As discussed in that Section, although the rotary drilling equipment used for raise bore operations produce high levels of vibration, much of this activity would occur many feet below ground entirely within bedrock. Vibration sources in rock tend to result in low amplitudes of vibration levels.

Typical vibration levels for other construction equipment, similar to that being proposed for use at the Shaft Site, are shown in Table 6.13-1. Values provided for caisson drilling are representative of those for the proposed pile drill rig and soil compactor. Levels shown for jackhammers are similar to or greater than those that can be expected for rock drilling and pneumatic hammering.

The values provided in the table are based on the literature. Actual vibration levels are dependent on construction procedures, soil and geological conditions, and the structural characteristics of the receptor (e.g., foundation and construction type).

Notes: PPV at 25 feet are based on FTA 1995. To calculate PPV at other distances, the following equation (FTA 1995) was used:

\[ \text{PPV at Distance D} = \text{PPV (at 25 ft)} \times \left(\frac{25}{D}\right)^{1.5} \]

The closest sensitive structures to this site are residences located across E. 59th Street from the Queensboro Bridge. For the residential apartment buildings across E. 59th Street, which are approximately 86 feet from the edge of the shaft chamber, PPV levels are expected to be well below the 2.0 ips threshold to avoid structural damage and below the 0.5 ips threshold to protect more fragile structures, or against cosmetic/architectural damage. This would be expected to be the case even with more than one piece of machinery operating. The contractor will be required to have a vibration control plan and monitoring program in place during all construction activities. Some of the construction for the water main would overlap with construction of the shaft. Since the water main work does not involve blasting, the combined effects of more than one piece of machinery operating would not change the results of this assessment.

With regard to the Queensboro Bridge (at a distance of 12 feet from the edge of the shaft chamber), measures based on actual Site conditions will be put in place to ensure that there are no adverse vibration impacts to the Queensboro Bridge, a historic and critical transportation structure. For a discussion of these measures, see Section 4.13, “Vibration,” in Chapter 4, “Preferred Shaft Site.”

There is the potential that, at times, vibration effects would reach levels that would be annoying to residents in nearby buildings. These buildings contain ground floor commercial uses and vibration levels are likely to be lower on the second floor and above, where the residences are located, depending on the building construction. Much of the vibrating equipment, such as rock drills, the raise bore, and pile drilling rig would be used below the ground surface where additional distance and ground attenuation would reduce vibration levels. Lastly, much of the vibration-causing construction equipment would be used on an intermittent basis during the construction period.

Conclusions

With implementation of the measures discussed above, vibration levels during construction would be limited to levels that would not cause structural damage. However, at times, vibration levels would still occur at levels that would be likely to cause annoyance to residents and other
sensitive receptors in the immediate vicinity of this site. Blasting, which would cause the most intrusive vibration effects, would occur over a period of 8 months for the raise bore method and 24 months for the surface excavation method. Other vibration-causing construction equipment would be used on an intermittent basis during the construction period or would be used primarily below the surface. These potential impacts are considered short-term and temporary in nature. The contractor will be required to have a vibration control plan and monitoring program in place during all construction activities. Therefore, no potential significant adverse vibration impacts would be anticipated to occur from construction of the shaft and its water main connections at E. 59th Street and Second Avenue.

**Operation**

None of the activities associated with the activation or operation of this Shaft would cause potential vibration impacts, as there would be no significant vibration-causing machinery associated with these activities. Therefore, no potential significant adverse impacts are anticipated to occur.
