Preventing and Managing Overweight and Obesity in Adults

- Assess weight status periodically by weighing patients and calculating their body mass index (BMI).
- Develop a realistic weight-loss plan with your patients; focus on a reduced-calorie diet, regular physical activity, and behavioral support.
- Promote healthy lifestyle choices for life-long weight management.

Obesity and overweight are epidemic in New York City (NYC) and across the country. About two thirds of the US population are overweight or obese, including more than half (about 3 million) of the adults in NYC. More than 100,000 deaths a year nationwide are directly attributed to obesity, and increased body weight is associated with higher all-cause mortality. The key modifiable behavioral factors in obesity—unhealthy diet and physical inactivity—are second only to smoking as causes of premature death in the US.

Being overweight or obese increases the risk of type 2 diabetes, heart disease, stroke, gall bladder disease, osteoarthritis, sleep apnea, respiratory problems, and colon, breast, endometrial, and prostate cancers. Other health consequences include compromised psychological well-being along with social stigmatization and discrimination.

Obesity-Related Disparities in New York City
- In NYC, women are more likely than men to be obese (23% vs. 20%).
- The poorest New Yorkers are more obese than the wealthiest (29% vs. 16%).
- Black and Hispanic New Yorkers of all income levels are more likely to be obese than white New Yorkers. Even among residents with household incomes ≥$50,000, nearly twice as many blacks and Hispanics are obese than whites (23% vs. 12%).
- Poorer New Yorkers are less likely to exercise, regardless of race/ethnicity.

The dramatic doubling in obesity rates among US adults—from 15% to 32% between 1971 and 2004—cannot be explained by changes in genetic factors. Rather, changes in nutrition, physical activity, and environmental factors are key contributors to this epidemic. Weight gain-inducing behaviors include sedentary lifestyle, consuming a diet high in calories, relying on food prepared and eaten outside the home, and excessive intake of high-calorie beverages. Environmental factors that influence these behaviors include poverty, heavy marketing of unhealthy foods and large portion sizes, and the construction of neighborhoods that discourage physical activity.

Weight gain occurs incrementally over time; between 1990 and 2000, US adults gained an average of 1 pound per year. Given this insidious process, it is critical that clinicians carefully monitor weight in their patients and help them modify weight gain-inducing behaviors.
5 Steps to Preventing and Managing Overweight and Obesity in Primary Care

1. Assess weight status with body mass index (BMI).
2. Assess risk factors and comorbidities.
3. Recommend weight loss for overweight and obese patients.
4. Assess barriers to weight loss.
5. Formulate a weight loss plan that focuses on healthy eating and physical activity.

1. ASSESS WEIGHT STATUS IN ALL ADULTS

Screen all adult patients for overweight and obesity by weighing them and calculating their BMI using the following formula:

\[
\text{BMI} = \frac{\text{Weight (kg)}}{\text{Height (m)}^2} \quad \text{OR} \quad \frac{\text{Weight (lbs) \times 703}}{\text{Height (inches)}^2}
\]

An online BMI calculator can be found at: www.nhlbisupport.com/bmi.

Table 1 displays BMI categories; Figure 1 will help you to quickly assess weight status. Use clinical judgment interpreting the BMI; it may be skewed by edema, high muscularity, muscle wasting, or short stature.

In addition to BMI, a large waist circumference is an independent risk factor among patients with a BMI under 35 kg/m\(^2\). A waist circumference of >40 inches in men and >35 inches in women increases the risk of type 2 diabetes, dyslipidemia, hypertension, and cardiovascular disease because of excess abdominal fat.\(^7\)

2. ASSESS RISK FACTORS AND COMORBIDITIES

The need for weight loss is particularly critical when other risk factors and/or comorbidities are present. A comprehensive history and physical exam are essential to assess risk factors and comorbidities.

<table>
<thead>
<tr>

</tbody>
</table>

*Some Asian populations may be at increased risk for type 2 diabetes and cardiovascular disease at BMIs ≥25 kg/m\(^2\). The cut-off point for increased risk ranges from 22 kg/m\(^2\) to 25 kg/m\(^2\) in different Asian populations.\(^8\)

Identify patients at very high risk for complications, including death. These patients may have:

- Established coronary heart disease, including a history of myocardial infarction, angina, coronary artery surgery, or coronary artery procedures (e.g., angioplasty);
- Presence of other atherosclerotic disease, including peripheral arterial disease, abdominal aortic aneurysm, or symptomatic carotid artery disease;
- Type 2 diabetes;
- Sleep apnea.

Identify other risk factors that increase risk for cardiovascular disease, including:

- Cigarette smoking;
- Physical inactivity;
- Age—men ≥45 years and women ≥55 years (or postmenopausal);
- Fasting glucose between 110 and 125 mg/dL, or impaired glucose tolerance (OGTT between 140 and 199 mg/dL);
- Hypertension (or blood pressure controlled with medication);
- Low-density lipoprotein (LDL) ≥160 mg/dL;
- High-density lipoprotein (HDL) <35 mg/dL;
- Triglycerides ≥200 mg/dL.
Lifestyle counseling is important for all patients.

Physical activity and healthy eating decrease risks for chronic disease, regardless of weight or weight loss. Counsel all patients to eat a healthy diet and to get at least 30 minutes of moderate-intensity physical activity at least 5 days a week, preferably every day. Moderate-intensity activities, such as brisk walking, bicycling, vacuuming, and gardening cause small increases in breathing or heart rate. Suggest the following weight management tips:

- Avoid high-calorie beverages, including juice.
- Eat less fast food.
- Eat more fruits and vegetables.
- Limit portion sizes.
- Incorporate physical activity into daily life.

Other conditions associated with obesity include gynecological abnormalities (e.g., menorrhagia, amenorrhea, polycystic ovarian syndrome), gallstones, osteoarthritis, gout, stress incontinence, and decreased quality of sexual life.

Rule out potential causal factors, such as medical conditions (e.g., hypothyroidism, depression) and current medications, that may induce weight gain. Medications that cause weight gain are particularly common in the treatment of diabetes, mood disorders (e.g., depression, bipolar disorder), and psychotic disorders (e.g., schizophrenia) (see Table 2, page 27, for a list of weight gain-inducing medications and alternatives).

3. RECOMMEND WEIGHT LOSS IN OVERWEIGHT AND OBESE PATIENTS

Inform overweight or obese patients of their weight status and recommend weight loss. Provide the patient with information on their risk for chronic disease based on an individual risk assessment (Step 2, page 24) and on the benefits of weight loss. Discuss weight status with sensitivity and attention to potential stigma (Table 2).

Weight loss has many potential benefits. Tell your patients that weight loss can:

- Lower elevated blood pressure;
- Lower elevated levels of total cholesterol, bad cholesterol (LDL), and triglycerides, and raise low levels of good cholesterol (HDL) in those with dyslipidemia;
- Lower elevated blood glucose levels in patients with type 2 diabetes, and prevent or delay the onset of type 2 diabetes in those who do not yet have the disease. In patients with pre-diabetes, a 5% weight loss (about 10–15 lbs) and at least 30 minutes of physical activity 5 days a week reduced the risk of developing diabetes by nearly 60%.

In addition to improving a patient’s medical profile, weight loss can make a person feel more confident and comfortable in social situations.

4. ASSESS BARRIERS TO WEIGHT LOSS

Weight loss is challenging for most patients. Many will face such obstacles as:

- Lack of motivation;
- Time constraints;
- Lack of understanding of risks and benefits;
- Lack of support from family and friends;
- Financial constraints;
- Lack of a feasible plan for making lifestyle changes;
- Lack of access to places for exercise;
- Lack of access to markets that sell healthy foods;
- Family eating patterns;
- Negative attitudes toward physical activity;
- Stigma and weight bias (resulting in inaction).

Understanding these issues and helping patients address potential obstacles will increase the likelihood of success. Even if patients are not ready to lose weight, encourage them to set manageable goals to improve their diet and/or raise their level of physical activity. Healthy behaviors prevent chronic diseases and can help stabilize weight over time.

5. FORMULATE A WEIGHT-LOSS PLAN

The initial goal of weight loss therapy is a 10% reduction in body weight over 6 months. Weight loss should be gradual—1 to 2 pounds, or 1% of body weight, per week. If additional weight needs to be lost after the initial 6-month period, set new targets.

A combination of a reduced-calorie diet, regular moderate-to vigorous-intensity physical activity, and support for lifestyle changes is the cornerstone of weight loss and maintenance and the safest strategy for both. Other approaches to weight management include drug regimen changes (if obesity is drug-induced), pharmacotherapy, and weight-loss surgery.

Table 2. Weight Issues Are Sensitive

| • Weigh patients in a private setting and record weight without judgment or comment. |
| • Ensure that medical equipment (e.g., gowns, blood pressure cuffs, scales, speculums) is appropriately sized to accommodate obese patients. |
| • Be sensitive when initiating discussion on weight (e.g., “Being overweight puts you at risk for a number of health problems. Mrs. Smith, could we talk about your weight today?”). |
| • Avoid hurtful or offensive descriptors (e.g., “fatness,” “weight problem”). |
| • Use interactive, empathic communication to enhance self-confidence and behavior change (e.g., “How are you feeling about your weight at this time? What are your goals now? What are some practical steps you can take to help meet these goals?”). |
Consider drug therapy only when patient is at increased medical risk due to weight (e.g., serious comorbidities, such as diabetes or sleep apnea).

Recommended criteria for considering bariatric surgery vary, ranging from BMI ≥35 with comorbidities to BMI ≥40 with comorbidities.

Table 3 outlines weight-loss treatment options with consideration given to initial BMI and the presence of serious comorbidities due to weight.

**Physical activity**

Regular physical activity plays an important role in weight loss and maintenance. Regular exercise also increases cardiorespiratory fitness and may decrease abdominal fat. Even patients who are unable to meet weight targets can significantly decrease their risk of chronic diseases with consistent moderate- to vigorous-intensity physical activity.

Assess patients’ current physical activity levels by asking about frequency, duration, and types of physical activity (including walking for transportation). Prescribe a physical activity plan on a prescription pad to convey the importance of physical activity in a weight loss and maintenance plan.

Evaluate patients with high-risk conditions (e.g., diabetes, cardiovascular disease, stroke, uncontrolled hypertension) to determine an appropriate exercise program. The decision to order exercise testing should be based on a patient’s age, symptoms, and concomitant risk factors.

Indications for exercise testing include:

- Known cardiovascular disease, including cardiac disease, peripheral vascular disease, and cerebrovascular disease;
- Known heart murmur;
- Known pulmonary disease, including chronic obstructive pulmonary disease, asthma, interstitial lung disease, and cystic fibrosis;
- Known metabolic disease, including type 1 or type 2 diabetes, thyroid disorders, and renal or liver disease;
- One or more signs or symptoms suggestive of cardiovascular and pulmonary disease, including pain (or any other anginal equivalent) in the chest, neck, jaw, or arms that may be due to ischemia; shortness of breath at rest or with mild exertion; syncope; orthopnea or paroxysmal nocturnal dyspnea; ankle edema; palpitations or tachycardia; intermittent claudication; and unusual fatigue or shortness of breath with usual activities.

At least 30 minutes of moderate-intensity physical activity is recommended a minimum of 5 days a week, preferably every day. For many patients, this level of activity may not be enough to produce significant weight loss and prevent weight regain. For these patients, recommend at least 40 to 60 minutes of moderate- to vigorous-intensity activity 5 or more days a week. Work with each patient to find a physical activity level that achieves weight control.

* Consider drug therapy only when patient is at increased medical risk due to weight (e.g., serious comorbidities, such as diabetes or sleep apnea).

† Recommended criteria for considering bariatric surgery vary, ranging from BMI ≥35 with comorbidities to BMI ≥40 with comorbidities.

**Prescribe a physical activity plan on a prescription pad to convey the importance of physical activity.**

Daily physical activity does not have to be accomplished all at once. Accumulating activity in 10-minute segments results in health benefits. Advise patients to build as much physical activity as possible into their daily routines. Two extra minutes of stair climbing each day can burn the equivalent of 1.6 pounds a year, enough to mitigate the average yearly weight gain in American adults. Table 4 describes simple steps patients can take to increase their daily physical activity. For most patients, walking is the most feasible form of physical activity.

Social support (e.g., buddy activities, walking groups) helps people increase physical activity. Provide resources such as fitness resource directories that include information about free and low-cost physical activity programs.
Dietary change

Adherence to a reduced-calorie diet is essential to weight loss. A reduction of 500 to 1,000 calories per day will result in a loss of 1–2 pounds per week. For women, this often means a diet containing 1,000 to 1,200 calories/day; for men, this means 1,200 to 1,600 calories/day.7

Assess the patient’s current diet to identify opportunities for caloric reduction. It may be helpful to have patients keep a food diary for a few days so that you can identify areas where they can cut back. Common sources of extra calories include:

- High-calorie beverages (non-diet soda, sugar- and fat-laden coffee drinks, fruit drinks and juices, “energy” drinks, alcoholic beverages);
- High-fat and/or high-calorie foods (e.g., “fast food,” deep-fried foods, chips, cookies, candy, bagels);
- Large portion sizes (e.g., restaurant meals).

Table 4 describes steps patients can take to reduce daily caloric intake. Addressing simple issues such as beverage choice can be an important first step. If appropriate, refer patients to a dietitian for more in-depth dietary counseling and support.

<table>
<thead>
<tr>
<th>Physical Activity</th>
<th>To lose weight and to prevent weight regain, work up to at least 40 to 60 minutes of moderate- to vigorous-intensity activity 5 or more days a week.* Daily physical activity can be broken down into 10-minute segments. Every minute of activity burns calories. Avoid injury and build endurance by starting slowly and increasing physical activity over time. Include as much brisk walking as you can in your daily routine.</th>

### *To how you eat.

- Control portion size by using smaller plates and bowls.
- Avoid eating in front of the TV.
- Don’t skip meals, especially breakfast.
- Prepare more meals at home.

Everyone should eat a moderate, healthy diet to prevent weight gain over time and reduce the risk of chronic disease.

*Moderate-intensity activities cause small increases in breathing or heart rate and include brisk walking, bicycling, vacuuming, and gardening. Vigorous-intensity activities cause large increases in breathing or heart rate (i.e., to the point where it is difficult to hold a conversation). Such activities include running and aerobics.*7
Support for lifestyle change

Behavioral support is an important adjunct to a comprehensive weight loss and weight loss maintenance plan. There is evidence that intensive counseling about diet and exercise, together with behavioral interventions aimed at skill development, motivation, and support strategies, produces sustained weight loss in adults who are obese.21

After assessing a patient’s barriers to weight loss (Step 4, page 25), work with the patient to address those barriers. Help the patient set small, achievable behavioral goals. Many patients want more help with weight management than they receive from their primary care physicians.22 Refer patients who need more support, particularly those at high medical risk, to a behavioral therapist and/or group weight loss program.

Drug regimen considerations

Because some medications can cause weight gain, review all medications a patient is taking and consider weight-neutral or weight loss-promoting alternatives (see Table 5). If a weight gain-inducing drug cannot be avoided, emphasize the need for regular physical activity and healthy eating. When the weight gain-inducing drug is an antidepressant or mood stabilizer, physical activity can also help relieve symptoms of depression and anxiety and improve mood.23

Be aware that medications, particularly glycemic and blood pressure control drugs, may need to be modified with any caloric restriction, increased physical activity, or weight loss.

Drug therapy

Use drug therapy as an adjunct to behavior change only for patients who are at increased medical risk and who have not met reasonable weight loss goals after 6 months of behavior change strategies. Drug therapy results in a net weight loss of 4 to 22 pounds, with most weight loss occurring within the first 6 months of treatment.2 See Table 6 for FDA-approved weight loss drugs. The safety and effectiveness of these medications have not been established for use beyond 2 years.24

Weight loss drugs may have serious adverse effects; prescribe them with caution (Table 6). Before prescribing, talk to your patient about adverse effects, lack of long-term safety and effectiveness data, and the temporary nature of weight loss achieved by medications.26 Sibutramine is contraindicated in many patients,27 and some studies have raised safety concerns with both sibutramine28,29 and orlistat.25,26 Closely monitor patients on drug therapy. Not every patient will respond even with an increase in dose.2

Diethylpropion, mazindol, benzphetamine, phenyltrazine, and phentermine are still on the market for short-term use. Two appetite-suppressant medications, fenfluramine and dexfenfluramine, were withdrawn from the market in 1997 after being linked to the development of valvular heart disease and primary pulmonary hypertension. The possibility that phentermine may be associated with primary pulmonary hypertension cannot be ruled out.26

*Off-label uses of drugs are not listed in the table.
†Metformin is the first-line pharmacologic treatment for type 2 diabetes unless contraindicated.

The use of brand names does not imply endorsement of any product by the New York City Department of Health and Mental Hygiene.
Herbal preparations and supplements are not recommended. They are unregulated and have potentially harmful and unpredictable effects. FDA consumer alerts have been issued against some herbs, including products containing ephedra, aristolochic acid, and herbal weight-loss tea.

Bariatric surgery

Bariatric surgery, including vertical-banded gastroplasty and Roux-en-Y gastric bypass, is an option for carefully selected patients who are at increased medical risk, and who have had no sustainable success with diet, exercise, and behavior modification. Recommendations for considering bariatric surgery vary. The National Heart, Lung and Blood Institute (NHLBI) recommends that surgery be considered for those with a BMI ≥35 with comorbidities or a BMI ≥40 regardless of the presence of comorbidities. The American College of Physicians recommends that surgery be considered for those with a BMI ≥40 with comorbidities.

An average weight loss of 20 kg (44 lbs) for surgically treated patients at 8 years of follow-up was observed in one study. Obesity-associated conditions such as type 2 diabetes, dyslipidemia, hypertension, and obstructive sleep apnea are improved or reversed in the majority of patients. Bariatric surgery is also associated with a reduction in mortality.

Bariatric surgery has significant risks. A recent report found the 30-day mortality rate to be 1.9%. In another study, nearly 40% of patients required re-admission or emergency department visits during the 6 months following bariatric surgery. Operative complications include anastomotic leak, subphrenic abscess, splenic injury, pulmonary embolism, wound infection, and stoma stenosis. Later complications include incisional hernias, gallstones, and dumping syndrome.

If a patient is a potential candidate for bariatric surgery, discuss surgery-related issues, including long-term side effects and the need to alter one’s eating habits after surgery. Refer potential candidates for surgery to a high-volume center with experienced bariatric surgeons, as mortality and complication rates decrease with the volume of procedures performed.

Summary

More than half of all NYC adults are overweight or obese. Behavioral changes, including healthier eating and regular physical activity, are the cornerstone of any weight loss program. Primary care physicians can help patients adopt gradual lifestyle changes to lose weight, maintain weight loss, and reduce obesity-related illness and death.

DOHMH JOB OPENINGS: We seek doctors, nurses, administrators, social workers, and other public health professionals. Visit www.nyc.gov/health/careers to view openings.
1. DM is a 52-year old woman who has had diabetes for 6 years. She is 5’6”, weighs 200 pounds, and has a BMI of 32kg/m^2. Her last A1C was 9.4%. Of the several medications she takes for her diabetes, all can cause weight gain EXCEPT:
   A. Insulin
   B. Glipizide
   C. Pioglitazone
   D. Metformin

2. DM eats at a fast-food restaurant 5 times a week, drinks 16 oz of juice for breakfast, and has no time to exercise. All of the following changes can help improve her weight and health EXCEPT:
   A. Limiting fast food, deep-fried foods, and high-fat snacks.
   B. Drinking water, seltzer, or 1% or skim milk instead of non-diet soda, fruit drinks and juices, and high-fat milk.
   C. Getting off the bus or subway a stop or two early and walking.
   D. Cooking with partially hydrogenated oils instead of canola or olive oil.

3. AB is a 38-year-old man with diabetes, heart disease, and sleep apnea. He has a BMI of 42kg/m^2. All of the following are appropriate for the management of his obesity EXCEPT:
   A. Developing a weight loss plan emphasizing healthy eating and physical activity.
   B. Immediately starting medications such as orlistat or sibutramine because his obesity is so severe.
   C. Setting a weight loss goal of 10% of total body weight over 6 months.
   D. Discussing bariatric surgery if, after a year of diet and exercise with intensive counseling, he is unable to meet his weight loss goals.

4. DM is having trouble sticking to an exercise plan. Her doctor should support this lifestyle change by all of the following EXCEPT:
   A. Helping her identify and set small, achievable goals for physical activity.
   B. Recommending a walking buddy or group.
   C. Discussing potential barriers to exercising and working with her to address those barriers.
   D. Telling her the best thing for her to do is join a gym and get vigorous exercise such as aerobics.

5. It is important to discuss AB’s weight status with sensitivity and attention to potential stigma. His primary care physician should do all of the following EXCEPT:
   A. Weigh AB in a private setting without judgment or comment.
   B. Use a large cuff, a large gown, and a scale that accommodates more than 300 pounds.
   C. Tell AB that his fatness is unacceptable and instruct him on setting behavioral goals.
   D. Use empathic, interactive communication to help AB identify and set manageable goals for diet and physical activity.

6. How well did this continuing education activity achieve its educational objectives?
   □ A. Very well □ B. Adequately □ C. Poorly

Please print legibly.

CME Activity  Preventing and Managing Overweight and Obesity in Adults

Continuing Education Activity

This issue of City Health Information, including the continuing education activity, can be downloaded from the publications section at nyc.gov/health. To access City Health Information and Continuing Medical Education online, visit www.nyc.gov/html/doh/html/chi/chi.shtml.

Instructions
Read this issue of City Health Information for the correct answers to questions. To receive continuing education credit, you must answer 4 of the first 5 questions correctly.

To Submit by Mail
1. Complete all information on the response card, including your name, degree, mailing address, telephone number, and e-mail address. PLEASE PRINT LEGIBLY.
2. Select your answers to the questions and check the corresponding boxes on the response card.
3. Return the response card (or a photocopy) postmarked no later than May 31, 2008. Mail to:
   CME Administrator, NYC Dept. of Health and Mental Hygiene, 2 Lafayette, CN-65, New York, NY 10277-1632.

To Submit Online
Visit www.nyc.gov/html/doh/html/chi/chi.shtml to submit a continuing education test online. Once logged into NYC MED, use the navigation menu in the left column to access this issue of City Health Information. Your responses will be graded immediately, and you can print out your certificate.
Objectives

At the conclusion of the activity, the participants should be able to:

1. Identify and manage patients who are overweight or obese.
2. Counsel patients on lifestyle modification.

Accreditation

The DOHMH is accredited by the Medical Society of the State of New York to sponsor continuing medical education for physicians. The DOHMH designates this educational activity for a maximum of 1 AMA PRA Category 1 Credits™.

Each physician should claim only those hours of credit that were spent on the educational activity. Participants are required to submit name, address, and professional degree. This information will be maintained in the Department’s CME program database. If you request, the CME Program will verify your participation and whether you passed the exam.

We will not share information with other organizations without your permission, except in certain emergencies when communication with health care providers is deemed by the public health agencies to be essential or when required by law. Participants who provide e-mail addresses may receive electronic announcements from the Department about future CME activities as well as other public health information.

Participants must submit the accompanying exam by May 31, 2008.

CME Activity Faculty:
Diana K. Berger, MD, MSc; Karen K. Lee, MD, MHSc; Lynn D. Silver, MD, MPH

All faculty are affiliated with the New York City DOHMH, Division of Health Promotion and Disease Prevention.

The faculty does not have any financial arrangements or affiliations with any commercial entities whose products, research, or services may be discussed in this issue.
